

Lecture 20: Process Control

Philipp Koehn

October 26, 2020

601.229 Computer Systems Fundamentals

Control Flow

- ▶ The CPU executes one instruction after another
- ▶ Typically, they are next to each other in memory (unless jumps, branches, and returns from subroutine)
- ▶ Exceptional Control Flow, triggered by
 - ▶ hardware exception
 - ▶ software exception

Exceptions

- ▶ Interrupts
 - ▶ signal from I/O device
 - ▶ also: timer interrupts for multi-tasking

Exceptions

- ▶ Interrupts
 - ▶ signal from I/O device
 - ▶ also: timer interrupts for multi-tasking
- ▶ Traps and system calls
 - ▶ intentional
 - ▶ triggered by instruction ("syscall")

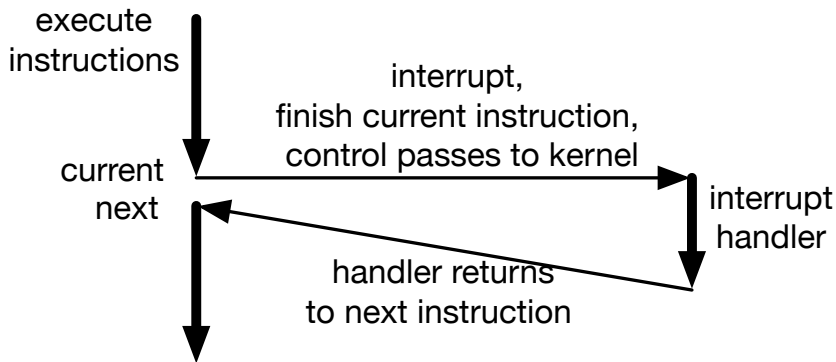

Exceptions

- ▶ Interrupts
 - ▶ signal from I/O device
 - ▶ also: timer interrupts for multi-tasking
- ▶ Traps and system calls
 - ▶ intentional
 - ▶ triggered by instruction ("syscall")
- ▶ Faults
 - ▶ maybe recoverable, e.g., swapped out memory ("page fault")
 - ▶ if recovered, return to regular control flow

Exceptions

- ▶ Interrupts
 - ▶ signal from I/O device
 - ▶ also: timer interrupts for multi-tasking
- ▶ Traps and system calls
 - ▶ intentional
 - ▶ triggered by instruction ("syscall")
- ▶ Faults
 - ▶ maybe recoverable, e.g., swapped out memory ("page fault")
 - ▶ if recovered, return to regular control flow
- ▶ Aborts
 - ▶ unrecoverable fatal error, e.g., memory corrupted
 - ▶ application process is terminated

Abrupt Change in Control Flow

Processes

Process

- ▶ Exceptions are the basic building block for processes
- ▶ Modern computers seem to run several things at once
 - ▶ retrieve and display web pages
 - ▶ play music in the background
 - ▶ accept emails and alert you to them

Process

- ▶ Exceptions are the basic building block for processes
- ▶ Modern computers seem to run several things at once
 - ▶ retrieve and display web pages
 - ▶ play music in the background
 - ▶ accept emails and alert you to them
- ▶ Process = a running program
 - ▶ appears to have full access to memory
 - ▶ appears to run without interruptions

Process

- ▶ Exceptions are the basic building block for processes
- ▶ Modern computers seem to run several things at once
 - ▶ retrieve and display web pages
 - ▶ play music in the background
 - ▶ accept emails and alert you to them
- ▶ Process = a running program
 - ▶ appears to have full access to memory
 - ▶ appears to run without interruptions
- ▶ Multi-tasking: modern OS that allow multiple processes at once

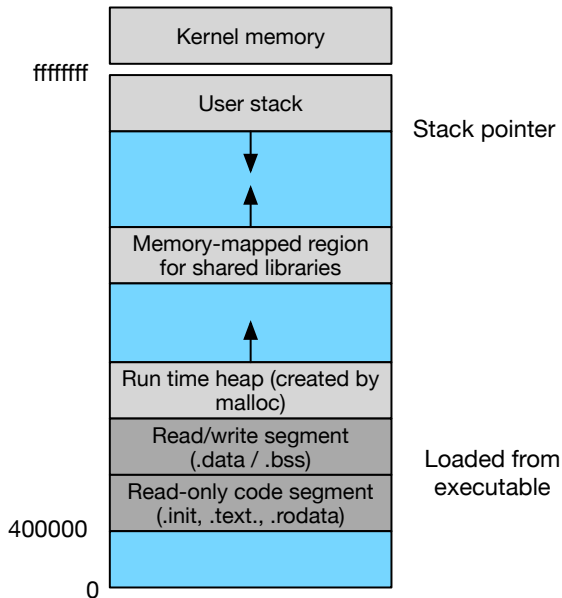

Logical Control Flow

User and Kernel Mode

- ▶ Mode bit in control register
- ▶ Kernel mode: may execute any instruction, access any memory
- ▶ User mode: limited to private memory
- ▶ Switch from user to kernel mode
 - ▶ voluntary (sleep)
 - ▶ triggered by interrupt
 - ▶ system call

Private Address Space

Process Context

- ▶ Kernel maintains context for each process
- ▶ Context
 - ▶ program counter
 - ▶ register values
 - ▶ address table (more on that soon)
 - ▶ opened files
 - ▶ various meta information (e.g., process name)
- ▶ In Linux, each process context viewable in `/proc` "file" system

Context Switches

System calls

Examples

| Number | Name | Description |
|--------|--------|--------------------------------------|
| 0 | read | read from file |
| 1 | write | write to file |
| 2 | open | open file |
| 3 | close | close file |
| 33 | pause | suspend process until signal arrives |
| 39 | getpid | get process id |
| 57 | fork | create new process |
| 60 | exit | end process |
| 61 | wait4 | wait for a process to terminate |
| 62 | kill | kill another process |

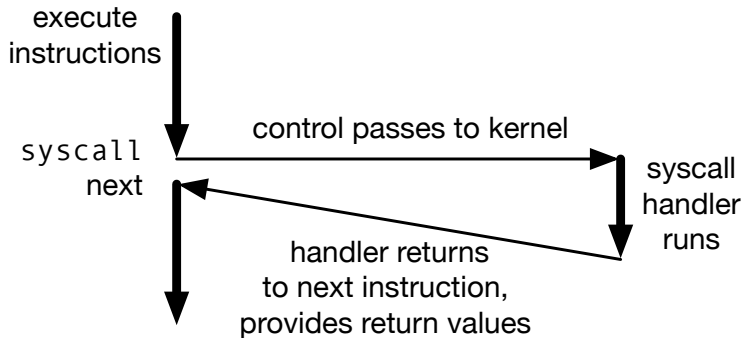

Assembly Example

```
.section .data
string:
    .ascii "hello, world!\n"
string_end:
    .equ len, string_end - string

.section .text
.globl main
main:
    movq $1, %rax        ; write is system call 1
    movq $1, %rdi        ; arg1: stdout is "file" 1
    movq string, %rsi     ; arg2: hello world string
    movq len, %rdx        ; arg3: length of string
    syscall

    movq $60, %rax       ; exit is system call 60
    movq $0, %rdi        ; exit status
    syscall
```

System Call Control

Zoom poll!

Which of these C library functions, when called, might result in a system call?
(Note: there could be multiple correct answers.)

- A. `printf`
- B. `malloc`
- C. `strcpy`
- D. All of A–C
- E. None of A–C

Process control

Creating New Processes

- ▶ C code that spawns a child process

```
int main() {  
    int x = 1;  
    pid_t  pid = fork();  
  
    if (pid == 0) {  
        printf("child x=%d", ++x);  
        exit(0);  
    }  
    printf("parent x=%d", --x);  
    exit(0);  
}
```

- ▶ When run, it returns
parent x=0
child x=2

Syscall 57: Fork

- ▶ `fork()` creates a child process
- ▶ Call once, return twice
 - ▶ in child process: return value 0
 - ▶ in parent process: return value is process id of child

Syscall 57: Fork

- ▶ `fork()` creates a child process
- ▶ Call once, return twice
 - ▶ in child process: return value 0
 - ▶ in parent process: return value is process id of child
- ▶ Concurrent execution
 - ▶ parent and child processes run concurrently
 - ▶ no guarantee which proceeds first (and for how long)

Syscall 57: Fork

- ▶ `fork()` creates a child process
- ▶ Call once, return twice
 - ▶ in child process: return value 0
 - ▶ in parent process: return value is process id of child
- ▶ Concurrent execution
 - ▶ parent and child processes run concurrently
 - ▶ no guarantee which proceeds first (and for how long)
- ▶ Duplicate by separate address space
 - ▶ initially memory is identical
 - ▶ each process makes changes to its private copy

Another Example

► Multiple forks

```
int main() {  
    fork();  
    fork();  
    printf("hello\n");  
    exit(0);  
}
```

Another Example

- Multiple forks

```
int main() {  
    fork();  
    fork();  
    printf("hello\n");  
    exit(0);  
}
```

- Outputs "hello" 4 times

Death in the Family

- ▶ What happens when what dies when?
- ▶ Child process dies
 - ▶ process still in kernel's process table
 - ▶ waiting for parent to read exit status
 - ▶ "zombie": dead, but still active
- ▶ Parent process dies
 - ▶ children processes become orphaned
 - ▶ orphan killing: terminate all orphaned processes
 - ▶ re-parenting: make init process (pid: 1) parent
(→ a "daemon" process)

Waiting for Child to Die

1. Parent spawns child process
2. Both processes running
3. Parent waits for child to complete
 - ▶ C: `waitpid()`
 - ▶ Assembly: `syscall 61`
4. Parent stalls
5. Child dies (zombie)
6. Parent receives exit status of child
7. Child dies completely

- ▶ Parent process may execute another program
 - ▶ C: `execve(filename, argv, envp)`
 - ▶ Assembly: `syscall 59`
- ▶ Passes environment variables (`envp`)
- ▶ Executed command takes over
- ▶ If both should run: `fork` first
