# Memory management

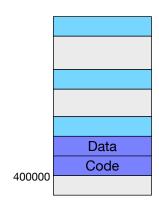

#### One Page Table per Process

### Process Address Space

# Simplified Linking

- ► Each process has its code in address 0x400000
- ► Easy linking: Linker can establish fixed addresses

### Simplified Loading

- ▶ When loading process into memory...
- ► Enter .data and .text section into page table

### Simplified Loading

- ▶ When loading process into memory...
- ► Enter .data and .text section into page table
- ► Mark them as invalid (= not actually in RAM)

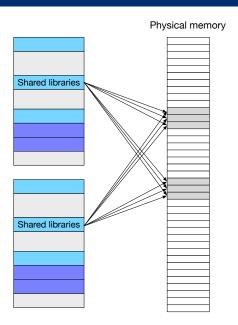

### Simplified Loading

- ▶ When loading process into memory...
- ► Enter .data and .text section into page table
- Mark them as invalid (= not actually in RAM)
- ► Called memory mapping (more on that later)

### Simplified Sharing

Shared libraries used by several processes: e.g., stdio providing printf, scanf, open, close, ...

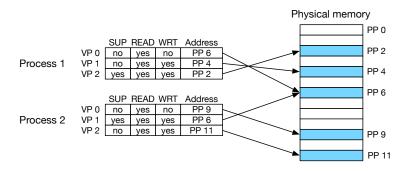

Not copied multiple times into RAM

### Simplified Memory Allocation

- ▶ Process may need more memory (e.g., malloc call)
- $\Rightarrow$  New entry in page table
- Mapped to arbitrary pages in physical memory
- ▶ Do not have to be contiguous

#### Memory Protection

- ► Page may be kernel only: SUP=yes
- ► Page may be read-only (e.g., code)

# Address translation

### Address Space

- ▶ Virtual memory size:  $N = 2^n$  bytes
- ▶ Physical memory size:  $M = 2^m$  bytes
- ▶ Page (block of memory):  $P = 2^p$  bytes
- ▶ A virtual address can be encoded in *n* bits

#### Address Translation

- ► Task: mapping virtual address to physical address
  - virtual address (VA): used by machine code instructions
  - physical address (PA): location in RAM
- ► Formally

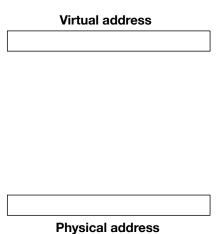

MAP: 
$$VA \rightarrow PA \cup 0$$

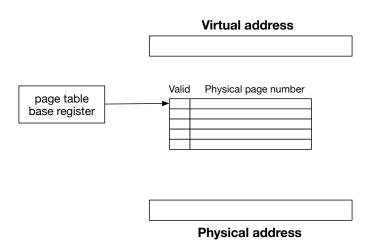

where:

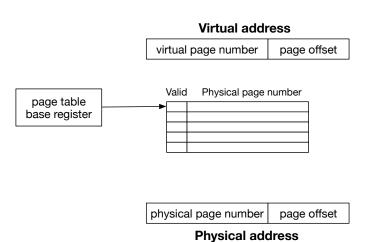

$$MAP(A) = PA \text{ if in RAM}$$
  
= 0 otherwise

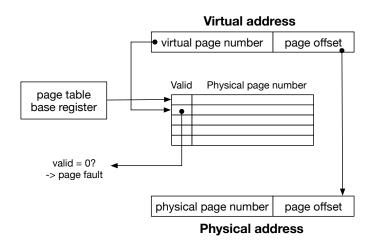

- ▶ Note: this happens very frequently in machine code
- ▶ We will do this in hardware: Memory Management Unit (MMU)

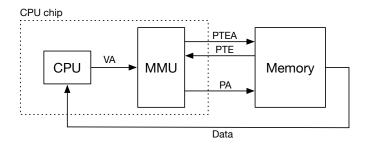

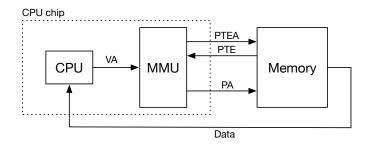

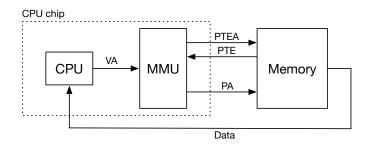

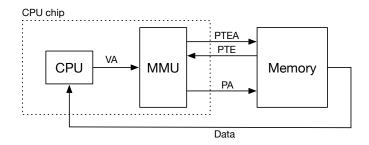

► VA: CPU requests data at virtual address

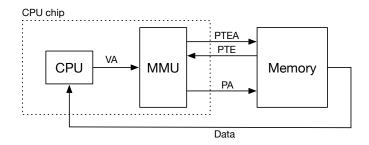

- ► VA: CPU requests data at virtual address
- ▶ PTEA: look up page table entry in page table

- ► VA: CPU requests data at virtual address
- ▶ PTEA: look up page table entry in page table
- ▶ PTE: returns page table entry

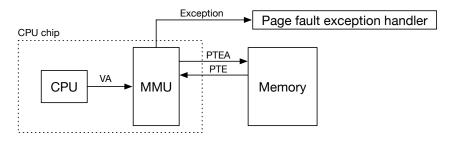

- ► VA: CPU requests data at virtual address
- ▶ PTEA: look up page table entry in page table
- ► PTE: returns page table entry
- ▶ PA: get physical address from entry, look up in memory

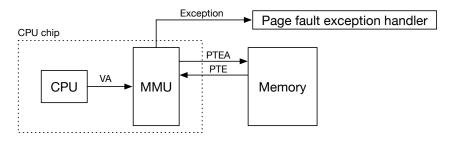

- ► VA: CPU requests data at virtual address
- ▶ PTEA: look up page table entry in page table
- ► PTE: returns page table entry
- ▶ PA: get physical address from entry, look up in memory
- ▶ Data: returns data from memory to CPU

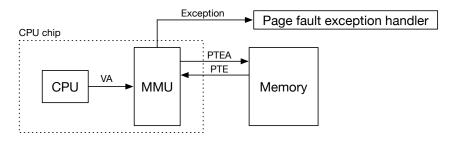

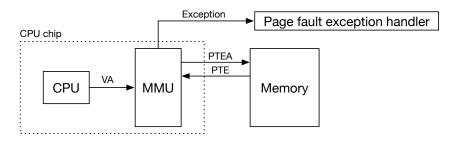

► VA: CPU requests data at virtual address

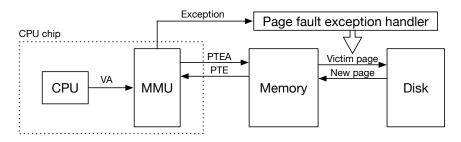

- ► VA: CPU requests data at virtual address
- ▶ PTEA: look up page table entry in page table

- ► VA: CPU requests data at virtual address
- ► PTEA: look up page table entry in page table
- ▶ PTE: returns page table entry

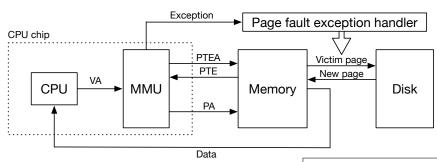

- ► VA: CPU requests data at virtual address
- PTEA: look up page table entry in page table
- ▶ PTE: returns page table entry
- Exception: page not in physical memory

- ► VA: CPU requests data at virtual address
- ▶ PTEA: look up page table entry in page table
- ► PTE: returns page table entry
- Exception: page not in physical memory
- ► Page fault exception handler

- victim page to disk
- new page to memory
- update page table entries

- ► VA: CPU requests data at virtual address
- ► PTEA: look up page table entry in page table
- ► PTE: returns page table entry
- Exception: page not in physical memory
- ► Page fault exception handler

- victim page to disk
- new page to memory
- update page table entries
- ► Re-do memory request

#### Page Miss Exception

- ► Complex task
  - identify which page to remove from RAM (victim page)
  - ► load page from disk to RAM
  - update page table entry
  - trigger do-over of instruction that caused exception
- ► Note
  - loading into RAM very slow
  - added complexity of handling in software no big deal

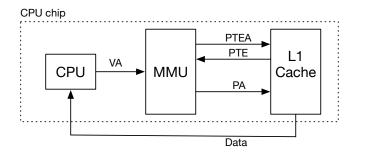

# Clicker quiz!

Clicker quiz omitted from public slides

- ► On-CPU cache
- ► Slow look-up time
- ► Huge address space
- ► Putting it all together

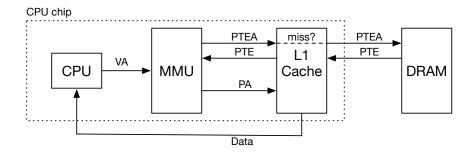

- ► On-CPU cache
  - ightarrow integrate cache and virtual memory
- ► Slow look-up time
- ► Huge address space
- ▶ Putting it all together

- ▶ Note
  - we claim that using on-disk memory is too slow
  - having data in RAM only practical solution
- ► Recall
  - we previously claimed that using RAM is too slow
  - ▶ having data in cache only practical solution
- ▶ Both true, so we need to combine

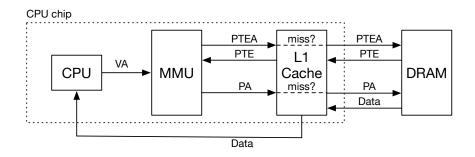

- MMU resolves virtual address to physical address
- ► Physical address is checked against cache

- ► Cache miss in page table retrieval?
- ⇒ Get page table from memory

- ► Cache miss in data retrieval?
- ⇒ Get data from memory

- ► On-CPU cache
  - $\rightarrow$  integrate cache and virtual memory
- ► Slow look-up time
  - → use translation lookahead buffer (TLB)
- ► Huge address space
- ► Putting it all together

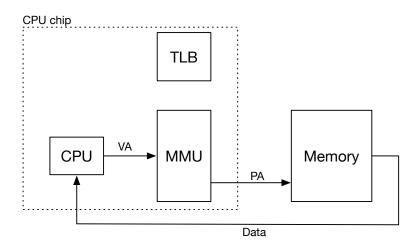

#### Look-Ups

- Every memory-related instruction must pass through MMU (virtual memory look-up)
- ▶ Very frequent, this has to be very fast
- ► Locality to the rescue
  - subsequent look-ups in same area of memory
  - look-up for a page can be cached

### Translation Lookup Buffer

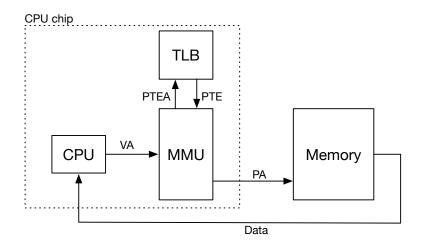

- ► Same structure as cache
- ► Break up address into 3 parts
  - ▶ lowest bits: offset in page
  - ▶ middle bits: index (location) in cache
  - ► highest bits: tag in cache
- Associative cache: more than one entry per index

#### Architecture

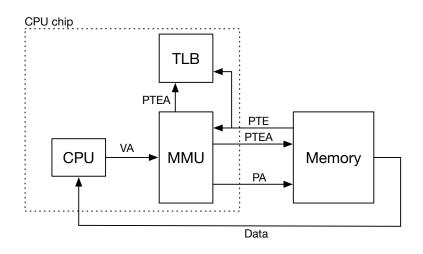

► Translation lookup buffer (TLB) on CPU chip

# Translation Lookup Buffer (TLB) Hit

► Look up page table entry in TLB

# Translation Lookup Buffer (TLB) Miss

- ▶ Page table entry not in TLB
- ► Retrieve page table entry from RAM
